Abstract Wastewater treatment is becoming ever more critical due to diminishing water resources, increasing wastewater disposal costs, and stricter discharge regulations that have lowered permissible contaminant levels in waste streams. The ultimate goal of wastewater management is the protection of the environment in a manner commensurate with public health and socio-economic concerns. The aim of our study is to use natural occurring polymeric coagulant to reduce the chemical oxygen demand and color from the industrial waste water. It was found that 83% of Chemical oxygen demand and 90% of color reduction was observed with chitosan.

Keywords: coagulation, filtration, polymeric coagulant, settling

1. Introduction

Industrialisation is back born for the growth of any nation. With increase in number of industry pollution level also increase which is the major problem for environmentalist. So many methods are available in the literature to treat the waste water. But due the cost of chemical and equipment industry have changeling to which one they adopt. Generally physicochemical treatment should be considered as cheaper method as compared to other. Physicochemical methods are effective when pollution level is low but depend upon the chemical used. Mostly organic, inorganic and polymeric are used to treat the waste water. Polymeric coagulant shows good performance especially when wastewater is more alkaline in nature. Polymers or polyelectrolyte's consist of simple monomers that are polymerized into high-molecular-weight substances [1] with molecular weights varying from 10^4 to 10^6 Daltons. Polymers can vary in molecular weight, the structure (linear versus branched), amount of charge, charge type and composition. The intensity of the charge depends upon the degree of ionization of the functional groups, the degree of copolymerization and/or the amount of substituted groups within the polymer structure [2,3]. With respect to charge, organic polymers can be cationic (positively charged), anionic (negatively charged) or nonionic (no charge). Polymers in solution generally exhibit low diffusion rates and raised viscosities, thus it is necessary to mechanically disperse the polymer into the water [4]. This is accomplished with short, vigorous mixing (velocity gradients, G values of 1500 sec^{-1} , although smaller values have been reported throughout the literature, 300 to 600 sec^{-1}) to maximize dispersion, but not so vigorous as to degrade the polymer or the flocs as they form [5].

1. Lower coagulant dose requirements,
2. A smaller volume of sludge,
3. A smaller increase in the ionic load of the treated water,
4. Reduced level of aluminum in treated water,
5. Cost savings of up to 25-30%.

Polyelectrolyte act in two distinct ways: charge neutralization and bridging between particles [6]. The mechanism of polymeric coagulant is shown in Figure 1. Because wastewater particles are normally charged negatively, low molecular weight, cationic polyelectrolyte's can act as a coagulant that neutralizes or reduces the negative charge of the particles, similar to the effect of alum or ferric chloride [7]. This has the effect of drastically reducing the repulsive force between colloidal particles, which allows the van der Waals force of attraction to encourage initial aggregation of colloidal and fine suspended materials to form microflocs [8]. The coagulated particles are extremely dense, tend to pack closely, and settle rapidly. If too many polymer is used, however, a charge reversal can occur, and the particles will again become dispersed, but with a positive charge rather than negatively charged [9].

The chemistry of wastewater has a significant effect of the performance of a polymer, the selection of a type of polymer for use as a coagulant/flocculation aid generally requires testing with the targeted waste stream, and the final selection is often more of an "art" than a science. Hundreds of polymers are available from numerous manufactures with a wide variety of physical and chemical properties. And, although the manufacturers can often help in a general way, the end user must often determine from all the various product line, which is best for their particular application and waste stream, i.e. most cost effective [10]. Chitosan is one of the natural occurring

polymeric coagulants, which is more effective in industrial waste water. Chitosan is a biopolymer, which is extracted from crustacean shells or from fungal biomass. In this regard's an effort has been made to treat the soap and detergent industrial waste water by using polymeric (Chitosan) for the reduction of chemical oxygen demand and color. The aim of work is to determine the optimum mass loading of chitosan with minimum mixing with time as well as reduction of physicochemical parameter.

Figure 1. Mechanism of polymer coagulation

2. Material and Method

2.1. Material

The waste water is arranged from soap and detergent industry whose parameter is given in Table 1.

Table 1. Parameters of Wastewater

S.NO	Parameter	Range mg/l
1	pH	8.8
2	BOD(Biochemical Oxygen Demand)	550
3	COD(Chemical Oxygen Demand)	1100
4	DO (Dissolve Oxygen)	0-2.0
5	TS (Total Solid)	570
6	TDS(Total Dissolve Solid)	400
7	SS (Suspended Solid)	220
8	Cl (Chloride)	45
9	S(Sulphur)	70
10	Oil & Grease	60
11	Colour	Dark yellow

2.2. Method

A 0.40dm³ of Food industry was taken in a 1.0 dm³ glass beaker, later on pH of the effluent was adjusted by adding aqueous NaOH (1 M) or H₂SO₄ (1 M) solution and mixed with glass rod for dispersion. The effluent and mixed for 5 min rapidly at 150 rpm, thereafter, slowly mixed for 30 min at 80 rpm. The effluent sample was then kept quiescent for 3 h. The supernatant liquor was taken and analysed for its COD value. These steps were repeated at different dosages of the coagulant. The settling and filtration characteristics of the slurry were also studied. Various parameters like COD, color, chlorine and protein were estimated as per standard parameter properties of various pollutants. The jar test apparatus is shown in Figure 2.

3. Result and Discussion

3.1. Effect of pH

pH is play important role for ionic reaction , the pH of the sample will decided the how much coagulant are effective. To determine the effectiveness of chitosan on wastewater sample, pH from 2 to 10 at 20 mm coagulant was used, which is shown Figure 3. It was observed that at pH 2, 3, 4, 5, 6 (acidic nature) the COD 30%, 33%, 35%, 37%, 40% and color 33.5%, 38.9%, 44%, 46.5%, 49% reduction respectively. The maximum percentage of COD 55% and color 62% reduction shows at pH 7. At pH 8, 9 and 10 the 48%, 39%, 31% of COD and 57%, 48%, 35% of color reduction was observed. It is due to at higher pH, chemical functional groups associated with organic are ionized and results in increasing of negative charge. Whereas, at lower pH there is no ionization of any functional groups and organic removal is achieved mainly due to adsorption. Analysis of the species of aluminum in water indicates that polycationic polymers predominate below pH 6 and hydroxide precipitate dominates in the pH range 6 to 9 [11]. The mechanism of pollution removal, therefore, is different under the different pH condition.

Figure 3. Effect of pH on COD and color reduction at pH_i = 8.8, massloading = 20 mm

3.2. Effect of Mass Loading

The removal of pollution fractions was dependent upon treatment conditions such as applied coagulant dose, pH, etc. and that treatment conditions can be optimized based

on the character of the organic matter present in the raw water [12]. To determine the effect of mass loading of chitosan at optimum pH 7 on wastewater sample is shown in Figure 4. The mass loading were varies from 20 mm to 60 mm. The maximum COD 83% and color 90% was found at 50 mm of chitosan. At initial when mass loading was 20 mm, 30 mm, 40 mm the COD 55%, 63%, 75% and color 62%, 71%, 78% was observed. Further increases in mass loading the COD 73% and color 76% were decreased. Over dosing of coagulant reduced the performance of treatment is due to restabilisation of colloids in effluent. In addition, coagulant overdosing will inevitably result in excessive sludge formation and increased chemicals and residuals management costs. In under dosing the amount of coagulant is not sufficient to neutralise the colloidal and optimum dosing mechanism of coagulation is relevant [13].

Figure 4. Effect of mass loading on COD and color at optimum pH=7

3.3. Effect of Mixing

Rapid mixing after coagulation is an important design parameter. The coagulant must be uniformly mixed with the raw water. In case mixing is poor local under- and overdosing occurs, resulting in poor performance of the process. The parameter expressing mixing intensity is called the velocity gradient. To determine the effect of mixing 50, 80, 120, 150 and 200 rpm on wastewater sample was carried out at pH 7 and mass loading 50 mm is shown in Figure 5. It was observed that at initial 50 rpm, 80 rpm, 120 rpm the COD 58%, 65%, 72% and color reduction 63%, 70%, 81% respectively. The maximum COD and color reduction 83% and 90% was found at 150 rpm at the beginning 5 minutes. Further increase in mixing speed 200 rpm decrease the COD 74% and color 79% reduction performance. Mixing intensity and time has significant effect on the mechanisms (e.g. sweep coagulation, sedimentation) involved in the following process of coagulation [14]. Between the hydrolysis of the coagulant in water and the development of large flocs, short-lived water soluble hydroxide complexes, metal hydroxide sols are formed, which also carry a positive charge [15]. The bond between the suspended solids to be removed and the polymeric sols and water soluble hydroxide complexes must be established within this short period. Rapid mixing of the coagulant will ensure rapid

hydrolysis of the coagulant, contact between the sols and the suspended solids and will retard the development of large flocs which are inactive in destabilizing the dispersion and removing of pollutant.

Figure 5. Effect of mixing on COD and color at optimum pH=7 and mass loading =50mm

3.4. Scanning Electron Microscope

The scanning electron microscope of wastewater before and after treatments was investigated which is shown Figure 6. It was found that before treatment without chitosan the sludge are look compact and rigid. After treatment with chitosan the sludge generated looks jelly type, it is due to structure of polymeric coagulant which are trapped the pollutant and bind up in like rope. Therefore the polymeric type's coagulants have more effective than the other coagulant.

Figure 6. Scanning Electron Microscope picture (a) before treatment (b) after treatment with chitosan at pH =7 mass loading =50mm, mixing 150 rpm

4. Conclusion

Chitosan was very much effective for the treatment soap and detergent wastewater. It proved that at pH 7 mass loading 50 mm and 150 rpm have capability to reduce the 83% of chemical oxygen demand as well as 90% of color. The scanning electron microscope shows that it has jelly structure which is better than other

coagulant. According to the study chitosan can be a good candidate to reduce the physicochemical parameters from wastewater. Chitosan may offer an alternative to traditional coagulants in wastewater treatment. The unique properties of chitosan together with availability make chitosan an exciting and promising agent for the pollution removal from wastewater.
